ABSTRACT OF THE DISCLOSURE

A urine sample collection device includes a receptor having a flared surface at an inlet area into which a user urinates, an elongate tubular member extending from the receptor and having an opening in one side thereof, and a coupling device connected with the tubular member adjacent the opening for releasably mounting a urine collection container. The collection device is characterized by a flow director located within the tubular member adjacent the opening and formed to direct urine past the opening. When the flow of urine exceeds the capacity of the flow director, urine enters the opening and the collection container. The device insures that mid stream urine (MSU) is collected.
